

## RELATED APPLICATION DATA

10 BACKGROUND

In the art it is known to monitor power supplied to home appliances. For example, Niles currently markets a power sensor under the “APC-2” brand name. Similarly, Panja markets a power sensor under the “AMX” “PCS” and “PCS2” brand names. These power sensors are particularly used to monitor the state of a home appliance, i.e., whether the home appliance is powered on or in a standby mode of operation (also referred to as off). More particularly, the power sensors are used in connection with a system that further comprises a central controller. The power sensors communicate state information to the central controller, via a hard wired connection, and the central controller is programmable to use the state information to effect control of home appliances.

While these known systems work for their intended purpose, they have not been widely adopted for use by consumers for the reason that they suffer numerous drawbacks. In this regard, the systems are expensive to purchase and installation (e.g., wiring of the components) often requires the assistance of a professional. Programming the central controller also requires a high-level of programming skill that most consumers find intimidating or are simply unable to comprehend. For example, the Niles system central controller is programmable only by authorized dealers/installers. Thus, the need exists for a system and method for controlling appliances having a power awareness component that an average consumer can afford to purchase and can easily use.

For simply controlling the operation of home appliances, it is also known to provide a remote control with macro command capabilities. For example, commonly owned U.S. Patent No. 5,959,751, which is incorporated herein by reference in its entirety, describes a method of programming a remote control to respond to activation of a macro key to cause the transmission of command codes that have been assigned to the macro key. Programming of a macro key can be accomplished by a consumer simply entering a macro setup mode, activating keys on the remote control in the same manner that the consumer would normally activate keys to cause one or more appliances to perform one or more operations, and exiting the macro setup mode. Macro keys can also be preprogrammed.

While remote controls having macro command capabilities have been widely accepted and used by consumers, there is a particular problem associated with the use of macros. When a macro is programmed to transmit power control commands to an appliance (e.g., a macro programmed to turn on a VCR, turn on a television, and tune the

television to channel 3), there is no easy way to ensure that the appliance is in a known state when the macro is executed. Thus, there is no easy way to ensure that the desired operations will be performed when the macro is executed. In the example provided, if the television were already powered on prior to executing the macro, executing the macro might send a power toggle command to the television that would not have the desired effect of turning the television on. Rather, to the frustration of a user, the power toggle command in the executing macro would cause the already powered on television to turn off and the tune to channel 3 command would not be capable of being operated upon by the now powered off television. Furthermore, if the associated VCR was initially powered off it would now be in the powered on state, placing the appliances “out of synch” such that a second activation of the macro function to turn the TV back on would cause the VCR to revert to the “off” state, to the even greater frustration of the user.

To solve this problem, it is possible for users to program a macro which omits the transmission of power commands. This, however, defeats the purpose of providing a remote control with macro command capabilities as the user must then control power to an appliance by conventionally activating keys on the remote control or by manually turning on/off the appliances. Alternatively, in limited cases where another function command also causes an appliance to turn on (e.g., most Sony AV receivers will turn on if not already on when an input select command is received) a macro can be programmed using these function commands to place the appliance in a desired state. This solution is also not generally acceptable as it requires the user to have a knowledge of the intricacies of the operation of an appliance which is knowledge that many consumers fail to possess. Furthermore, even if the consumer had such knowledge of appliance operation, this

solution requires that the appliance be placed in a state that might not be desired by the consumer thereby creating a further problem that needs to be addressed (e.g., by requiring the consumer to add further steps to a programmed macro). Accordingly, the need also exists for a system and method for controlling appliances that an average consumer can  
5 easily use and which will ensure that the desired operations will be performed.

It is further known in the art to provide various methods for configuring a remote control to command the functional operations of one or more home appliances. For example, U.S. Patent No. 5,614,906 describes a method for selecting a command set from a group of command sets, or library of command sets, stored in the memory of the remote  
10 control. From various of the command sets a command, whose effect is observable in a remotely controllable appliance, is selected and assigned to a user actuable key. The user may then press the actuable keys one by one until the user observes the desired effect on the remotely controllable appliance. The user may then manually signal the remote control to exit the configuration procedure with the remote control thus being  
15 configured to transmit future commands from the command set which includes the command that resulted in the controllable appliance performing the observed desired effect.

Still further, U.S. Patent No. 5,726,645 describes a system and method for configuring a remote control that relies upon a circuit that functions to detect the presence  
20 of audio signals emanating from a headphone jack of a television set. More particularly, the remote control is caused to sequentially transmit power commands to the television set that are selected from various command sets stored within the remote control. In accordance with the turning on or off of the television set, the circuit detects the transition

from a state wherein some audio signal is being output through the headphone jack to a state wherein no sound is output from the headphone jack or the opposite transition occurs. Upon the occurrence of a change in state of the headphone jack audio signal, the circuit transmits a detection signal to the remote control which, in turn, configures itself to utilize the command set including the most recently output command as the command set for controlling the television set. However, it will be appreciated that such a system and method will not be effective to configure a remote control in circumstances such as when the television set is muted, the volume level is not sufficient to be detected by the circuit, the appliance to be controlled does not have a headphone jack, or the like.

Accordingly, a need still exists for a more reliable system and method for automatically configuring a remote control to command the functional operations of multiple different types of home appliances.

## SUMMARY

In accordance with this need, a system and method for setting up a control device to command the operations of an appliance is described. Generally, the system includes a power monitor that is associated with the appliance – either integrally formed within the appliance or otherwise available for use by the appliance – and includes circuitry for determining a current power state of the appliance. The control device has a library of command code sets and includes programming for transmitting to the appliance a command code from one of the command code sets and for receiving from the power monitor a signal which indicates that the transmitted command code caused a change in the current power state of the appliance. If such a signal is received, the programming

functions to select the command code set which includes the command code to which the appliance responded by changing power states as the command code set for use in commanding the operations of the appliance.

5 A better understanding of the objects, advantages, features, properties and relationships of the system and method for using appliance power awareness to select a remote control command set will be obtained from the following detailed description and accompanying drawings which set forth illustrative embodiments which are indicative of the various ways in which the principles thereof may be employed.

## 10 BRIEF DESCRIPTION OF THE DRAWINGS

A system and method for using appliance power awareness to select a remote control command set will be described hereinafter with reference to the following drawings in which:

15 Figure 1 illustrates an exemplary system for providing a remote control with appliance power awareness;

Figure 2 illustrates a block diagram schematic of an exemplary remote control of the system of Figure 1;

Figure 3 illustrates a top view of the remote control of the system of Figure 1;

20 Figure 4 illustrates an exemplary table in which power state information is maintained by the remote control of the system illustrated in Figure 1;

Figure 5 illustrates an exemplary method for setting up the table of Figure 4 to enable the remote control of the system of Figure 1 to receive power state information;

Figure 6 illustrates an exemplary method for executing an update of the power state information table of Figure 4;

Figure 7 illustrates an exemplary method for commanding multiple appliances within the system of Figure 1 to be turned to the on state;

5        Figure 8 illustrates an exemplary method for commanding single appliances within the system of Figure 1 to be turned to the on state;

Figure 9 illustrates a block diagram schematic of an exemplary power monitoring unit of the system of Figure 1;

10       Figure 10 illustrates a schematic of an exemplary power monitoring module of the power monitoring unit of Figure 9;

Figure 11 illustrates an exemplary method for setting up a power monitoring unit of Figure 9 and for providing power state information to the remote control of the system of Figure 1;

15       Figure 12 illustrates an exemplary transmission sequence between the power monitoring units and the remote control of the system of Figure 1;

Figure 13 illustrates a further power monitoring unit in the form of a power strip;

Figure 14 illustrates a schematic diagram of the exemplary power monitoring unit of Figure 13; and

20       Figure 15 illustrates a flow chart diagram of an exemplary method for using the power monitoring unit to setup the remote control to command operations of an appliance.

## DETAILED DESCRIPTION

Turning now to the figures, wherein like reference numerals refer to like elements, there is illustrated in Fig. 1 a system for providing a remote control with appliance power awareness. Generally, the system includes a remote control 10 capable of commanding the operation of home appliances 12, such as television 12a and/or set-top box 12b. It will be appreciated that the home appliances 12 can be of different types (such as, by way of example only, televisions, VCRs, DVD players, set-top boxes, amplifiers, CD players, game consoles, home lighting, drapery, etc.) manufactured by different manufacturers. The home appliances 12 receive power from an electrical outlet 16 using an intermediate power monitor unit 14 having a socket for receiving the plug of an appliance 12 and a plug for insertion into a socket of the electrical outlet 16. As will be described in greater detail, the power monitor unit 14 communicates, either uni-directionally or bi-directionally, with the remote control 10 to provide the remote control 10 with awareness of the power state of a home appliance 12. In this manner, the remote control 10 can consider the power state of the home appliances when configuring itself to command functional operations of the home appliance, in executing a macro or other commands, and/or the like.

For communicating with the consumer appliances 12 as well as the power monitor units 14 (if bi-directional communication is desired), the remote control 10 preferably includes a processor 24 coupled to a ROM memory 26, a key matrix 28 (in the form of physical buttons, a touch screen, or the like), an internal clock and timer 30, an IR (or RF) transmission circuit 32 (for sending signals to a home appliance 12), an RF (or IR) uni-directional or bi-directional communications module 40 (for receiving and/or sending

signals from/to a power monitor unit 14), a non-volatile read/write memory 34, a visible LED 36 (to provide visual feedback to the user of the remote control 20), and a power supply 38 as illustrated in Fig. 2. As will be appreciated, the transmission circuit 32 and communications module 40 perform operations that could be performed by a single device. Accordingly, the transmission circuit 32 and communications module 40 need not be separate and distinct components.

The ROM memory 26 includes executable instructions that are intended to be executed by the processor 24 to control the operation of the remote control 10. In this manner, the processor 24 may be programmed to control the various electronic components within the remote control 10, e.g., to monitor the power supply 38, to cause the transmission of signals, etc. Meanwhile, the non-volatile read/write memory 34, for example an EEPROM, battery-backed up RAM, Smart Card, memory stick, or the like, is provided to store user entered setup data and parameters as necessary. While the memory 26 is illustrated and described as a ROM memory, memory 26 can be comprised of any type of readable media, such as ROM, RAM, SRAM, FLASH, EEPROM, or the like. Preferably, the memory 26 is non-volatile or battery-backed such that data is not required to be reloaded after battery changes. In addition, the memories 26 and 34 may take the form of a chip, a hard disk, a magnetic disk, and/or an optical disk.

For commanding the operation of home appliances of different makes, models, and types, the memory 26 also includes a command code library. The command code library is comprised of a plurality of command codes that may be transmitted from the remote control 10 for the purpose of controlling the operation of the home appliances 12. The memory 26 also includes instructions which the processor 24 uses in connection with

the transmission circuit 32 to cause the command codes to be transmitted in a format recognized by the target home appliance 12. Similarly, the memory 26 also includes instructions which the processor 24 uses in connection with the communications module 40 to cause communications to be transmitted in a format recognized by the power  
5 monitor units 14.

To identify home appliances 12 by type and make (and sometimes model) such that the remote control 10 is adapted to transmit recognizable command codes in the format appropriate for such identified home appliances 12, data may be entered into the remote control 10. Known methods for setting up a remote control to control the  
10 operation of specific home appliances include those described in, for example, U.S. Patent Nos. 5,614,906 and 4,959,810 which are incorporated herein by reference in their entirety. A yet further method for setting up a remote control 10 to control the operation of a home appliance will be discussed in greater detail hereinafter.

To cause the remote control 10 to perform an action, the remote control 10 is  
15 adapted to be responsive to events, such as a sensed user interaction with one or more keys on the key matrix 28. More specifically, in response to an event appropriate instructions within the memory 26 are executed. For example, when a command key is activated on the remote control 10, the remote control 10 may read the command code corresponding to the activated command key from memory 26 and transmit the command  
20 code to a home appliance 12 in a format recognizable by the home appliance 12. It will be appreciated that the instructions within the memory 26 can be used not only to cause the transmission of command codes to home appliances 12 but also to perform local operations. While not limiting, local operations that may be performed by the remote

control 10 include favorite channel setup, macro button setup, command function key relocation, etc. Since examples of local operations can be found in U.S. Patent Nos. 5,481,256, 5,959,751, 6,014,092, which are incorporated herein by reference in their entirety, they will not be discussed in greater detail herein.

5           By way of further example, an exemplary remote control 10 is illustrated in Fig. 3. While illustrated as a conventional hand-held remote control, the remote control can include other devices such as PDAs, personal computers, or the like. Accordingly, the description that follows need not be limiting. As illustrated, the remote control 10 includes a “Setup” key 310, a “Power” key 320, “Device” keys 330 (for selecting the mode of operation – i.e., the home appliance/device to control), “Numeric” keys 340 (corresponding to the digits 0-9), and a group of “Macro” keys 370 to which pre-programmed or user programmable macros can be assigned. Additional, optional keys may include a pair of keys 350 to command “All On” or “All Off” operations and/or a pair of keys 360 to command “On” and “Off” operations for a currently selected device. 15       The operation of the special keys 350 and 360, which comprise a smart power feature, will be described in greater detail in the paragraphs that follow. The remaining keys illustrated in Fig. 3 perform conventional remote control functions that will be well understood by those of ordinary skill in the art.

          For monitoring power supplied to a home appliance 12 and, accordingly, the state 20 of the home appliance 12 (e.g., powered on or off/in standby mode), the power monitoring unit 12 includes a current sensing device 50 as illustrated in Fig. 9. The current sensing device 50 may be in the form of a transformer having a primary winding 52 which is inserted in the path of current flow going from the outlet 16 to the home

appliance 12. In this manner, the transformer secondary winding 54 will thus have a current flow which is representative of the current flow passing through the transformer primary winding 52. In the illustrated current sensing device 50, a dropping resistor 56 is inserted as a load to convert the secondary winding 54 current to a voltage. It will be appreciated that other current sensing devices 50 for generating a signal representative of the current being drawn by the home appliance 12 may be used such as, by way of example only, any Hall Effect device.

For conditioning the signal generated by the current sensing device 50, the power monitor unit 14 may also be provided with a signal conditioning circuit 56. For example, the voltage drop across the resistor 56 can be sent through a signal conditioning circuit 56 comprised of an amplifier-rectifier 60/62 and a low-pass filter 64. In this manner, the AC voltage representation of the AC load current can be transformed to a DC voltage signal which can be interfaced to a processor 66 through an Analog-Digital (A/D) converter or Voltage to Frequency Oscillator (VFO). Further examples of such circuitry can be seen in "analog-digital CONVERSION HANDBOOK," Copyright 1972 & 1976 by Analog Devices, Inc.; Second Edition, June, 1976 and "IC Op-Amp Cookbook," by Walter G. Jung; 1974, 1980, and 1986 by Howard W. Sams & Co., A Division of Macmillan, Inc.; Third Edition - Fourth Printing, 1988. pp. 252 and 253, which are incorporated herein by reference in their entirety. The amplifier, rectifier and low pass filter are shown in greater detail in Fig. 10.

For powering the components of the power monitor unit 14, a voltage supply 72 is provided. By way of example, the voltage supply 72 can be circuitry that converts the AC voltage from the outlet 16 to a voltage level that can directly power the components

of the power monitor unit 14. Alternatively, the voltage supply 72 can be batteries. Still further, the power monitor unit 14 may include a small non-volatile memory (such as an EEPROM) to maintain setting through power failures, brown outs, etc.

5 The processor 66 has associated instructions for accepting the DC signal supplied from the conditioning circuit 58 and for performing operations based on the value of the signal. The processor 66 also has associated instructions which the processor 66 uses in connection with an RF (or IR) module to cause communications to be transmitted in a format recognized by the remote control 10. In this regard, RF transmissions can be made using any conventional protocol such as Bluetooth, etc. Instructions may also be  
10 provided for allowing the power monitor unit 14 to provide status information to a consumer by means of, for example, one or more LEDs 70, a display, etc. Once the power monitor unit is initialized, the power monitor unit enters a loop wherein it continually searches for one of at least two events, namely, activation of a user setup switch or receipt of a status enquiry message from the remote control 10.

15 To configure the power monitor unit 14 for use in the system, illustrated in Fig. 11, the power monitor unit 14 is set to recognize the “standby/off” and “on” load currents for the home appliance 12 associated with the power monitor unit 14. To this end, a consumer would place the appliance 12 to be monitored in the standby state and instruct the power monitor unit 14 to capture a signal representative of the current flow of the  
20 home appliance 12 in this standby state. The instruction to capture a signal representative of the standby current flow of the home appliance 12 can be entered by activation of a setup switch 74. In response to this instruction, the processor 66 monitors the DC voltage

signal from the conditioning circuitry 58 and stores this voltage signal as the representation of the standby current flow.

To setup the power monitor unit 14 to recognize the appliance on current flow, a consumer would place the appliance 12 to be monitored in the on state and instruct the power monitor unit 14 to capture a representation of the resulting current flow. The instruction to capture a representation of the standby current flow can be entered by activation of the setup switch 74. In response to this instruction, the processor 66 monitors the DC voltage signal from the conditioning circuitry 58 and stores this voltage signal as the representation of the on current flow. A threshold value may then be determined as the average of the on and off current flow representation values. It will be appreciated that these setup procedures can be timed to prevent the power monitor unit 14 from being locked in the setup mode of operation. It will be further appreciated that the setup procedure can be performed by the power monitor unit prompting the user to place the appliance in a given state and automatically monitoring the resulting current flow.

For use in establishing an address for the power monitor unit 14, which address is used to facilitate communications with the remote control 10, address setting device 76 is provided and accessible by the processor 66. The address setting device 76 may include dip switches, jumpers, means for keying in an address, or the like. In the case of dip switches or jumpers, the address setting device would be used to set a bit pattern that would serve as the address (e.g., three switches would allow the power monitor 14 to be set to one of eight unique addresses). Preferably, the address setting device 76 is accessible to the consumer although the address setting device can be factory preset. Additionally, extra switches 76 may be provided in cases where it is desired to set a

unique system address to allow multiple remote controllers 10 to operate independently in the same vicinity.

During the operation of the system, the power monitor units 14 are used to provide the remote control 10 with awareness of the current power state (i.e., on or off) of the one or more home appliances 12 the remote control 10 is setup to control. The remote control 10 may maintain the current power state of the home appliances 12 in a table 400, illustrated in Fig. 4, for further use in a manner to be described hereinafter. As illustrated in Fig. 4, the table 400 may maintain data for each device mode supported by the remote control 10. In the exemplary case, since the illustrated remote control includes eight device mode keys 330 the table 400 has eight data field rows 410. For each device mode 420 data may be maintained that is indicative of: 1) an ID (430) assigned to the power monitor 14 associated with the device 12 to be controlled in the given device mode; 2) a status of the device setup (440) within the remote control for the given device mode; and 3) a power status (450) for the device 12 as reported by its associated power monitor unit 14.

More specifically, the data field (430) maintains the unit address number that corresponds to the user-set address of the power monitor unit 14 associated with the device to be controlled in the given device mode. For example, in the illustrative table of Fig. 4, the remote control has been setup to control an appliance in the VCR device mode which has been indicated to be plugged into a power monitor unit 14 having an address of “3” and to control an appliance in the TV device mode which has been indicated to be plugged into a power monitor unit 14 having an address of “0.” It is to be understood that not all of the appliances 12 that the remote control 10 may control need a power

monitor unit 14 and, in the case where an appliance in a given device mode is indicated to be operating without a power monitor unit 14, the table 400 would maintain an entry of “none.” Preferably the table 400 is initialized when the remote control is first placed in service such that “none” is maintained in the data field 430 for each device mode 420  
5 until such time as the device mode is, in fact, setup to indicate an address for a power monitor unit.

To set the data in the ID data field 430 for a device mode 420, the user may perform the method generally illustrated in Fig. 5. By way of example, a user might enter a general setup mode (e.g., by activating the “Setup” key 310) followed by an  
10 indication to the remote control that the user specifically desires to setup the power module unit ID field of the table 400 (e.g., by entering a predetermined key sequence using the numeric keys 340, such as “979”). At this time the user may indicate to the remote control 10 the device mode of interest and the ID number of the power monitor unit associated with the appliance to be controlled in the given device mode (e.g., by  
15 hitting the appropriate “Device” key 330 and by hitting the numeric key 340 indicative of the address of the associated power monitor unit). The user could then indicate a desire to exit the setup mode (e.g., by again hitting the “Setup” key 310) at which time the indicated ID number would be stored in the data field 430 for the indicated device 420. This process can be repeated as often as needed to define the ID number of the power  
20 monitor unit for each device mode. This procedure may also be timed to prevent the remote control 10 from being locked in a setup mode. By way of an illustrative example, to setup the remote control such that the table 400 illustrated in Fig. 4 results, the user might hit the “Setup” key, enter the setup code “979,” and active the following keys: TV-

0-AMP-2-VCR-3-CD-1-AUX-4. The setup mode would be exited by again hitting the “Setup” key. In an alternative setup method discussed in greater detail later in this document, the remote control may issue a sequence of appliance commands of various formats while examining power monitor status in order to simultaneously ascertain the command format to which an appliance is responsive as well as the specific power monitor to which it is attached.

Within the table 400 in data field 440 may be further maintained data that is indicative of whether an appliance to be controlled in a given device mode has, in fact, been setup by a user. Setup in this context is with reference to the initial input by the user or automated process described hereinafter used to identify the specific brand/model of home appliance to be controlled when the corresponding “Device” button 330 is activated (*See for example* U.S. Patent Nos. 5,614,906 and 4,959,810). If no device setup has been performed for a given device mode the data field 440 for that device maintains data indicative of this fact, e.g., it maintains data representative of a state “No.” Preferably, upon initialization of the remote control 10, all of the data fields 440 are provided with a default value of “No” until such time as the device mode is setup. When a data field 440 indicates that a device mode has not been setup it may be assumed that the user does not have a home appliance to be controlled in this device mode and, as such, this device mode can be skipped during processing of an “All On” or “All Off” command which is described hereinafter.

A still further data field 450 within the data table 400 may hold the current power status (i.e., “on” or “off”) of a device as reported by its associated power monitor unit 14. If a device is not equipped with a power monitor unit 14 (i.e., the ID data field 430 has

data indicative of “none”) the data field 450 preferably maintains data indicating the appliance is in an “unknown” state. Likewise, if communications with the associated power monitor 14 have failed, the data field 450 again maintains data indicative of an “unknown” state.

5           To poll the one or more power monitor units 14 to gather the current power status, the remote control 10 issues a broadcast status enquiry message, as illustrated in Fig. 6, via its RF module 40. The power module units 14 respond to the status enquiry message by transmitting a status response message having data indicative of the status of the device associated with the respective power monitor unit 14. Preferably the status  
10   response messages from the one or more power monitor units 14 are transmitted in an orderly fashion to avoid collisions at the remote control 10. Upon receiving a status response message from a power monitor unit 14, received via the RF module 40, the remote control 10 strips the data from the status response message (i.e., the address of the responding power monitor unit 14 and the state of the device 12 associated with that  
15   power monitor unit 14) and updates the appropriate status data field 450 in the data table 400 to reflect the received status information. In the case where no response is received from a power monitor unit 14 or an invalid/untimely response is received, the power status of the data field corresponding to the missing or failed power monitor unit 14 is preferably set to “unknown.”

20           In responding to the status enquiry message received at the power monitor unit 14, the power monitor unit 14 measures the power draw of its associated home appliance as illustrated in Fig. 11. The measured power draw is then compared to the previously established threshold value. If the measured power draw is above the established

threshold value, the status of the home appliance 12 is determined to be “on.” If, however, the measured power draw is not above the established threshold value, the status of the home appliance 12 is determined to be “off.” It should be appreciated that while the power status determination method illustrated makes use of a fixed threshold value determined via a setup process, alternative embodiments in which the internal logic of the power monitor unit is adapted to dynamically report relative changes in power draw are equally feasible. For example the present power draw of an associated appliance may be compared against the last measured value and any significant change up or down (for example greater than  $\pm 25\%$ ) may be reported as a change in power status. This latter method may be advantageous in situations where, for example, users have not yet fully completed setup of their appliances, remote control and/or power monitor. This latter method may also be utilized in connection with monitoring variable power based appliance such as lighting dimmers and the like. Thus, it will be understood that such methods may be used in place of or in conjunction with absolute threshold comparisons. In each of these methods, a determined power status may be returned to the remote control 10 as data in the status reply message. The status reply message may also includes data that functions to identify the power monitor unit 14 transmitting the status reply message. Preferably this data is the address of the power monitor unit 14 which the power monitor unit 14 retrieves by reading the switches 76.

To prevent the collision of status reply messages at the remote control 10, each power monitor unit 14 may wait a unique time period before transmitting its reply message. By way of example, a power monitor unit 14 may wait a time equal to 20 milliseconds plus 100 milliseconds times its address number before transmitting the reply

message. Using a pre-transmit delay based on the unit address number in this manner results in each monitor 14 transmitting its status response in a sequential, predetermined manner (starting with unit 0 and ending with unit 7) as illustrated in Fig. 12. This further provides an additional level of error checking capability to the receiving remote control since each monitor unit 14 has a predetermined time window during which the remote control may expect to receive a reply transmission. Accordingly, receipt of a message outside of this time window would be indicative of an error condition resulting in the indication of an “unknown” state in the table 400 for the device associated with the power monitor unit 14 that is late with its transmission.

The polling of the power monitor units 14 may be initiated in response to the user activating one of the special power keys, one of the macro keys, in response to activation of a given setup mode, at timed intervals, etc. without limitation. For example, when the “All On” key is activated, the remote control transmits the status enquiry message and retrieves the power status of the devices from the power monitor units 14 as described above. Once the table 400 has been updated with the status of the devices, as illustrated in Fig. 7, the remote control 10 performs processing to command each device that has been identified to the remote control (i.e., setup) and which has a functioning power monitor unit 14 (i.e., a power status monitor address was setup in the remote control and the power status monitor has reported a current status) to enter the “On” state. In this regard, the transmission of the appropriate command signals to the appliances 12 (if necessary) may be performed in a sequential order following the order in which the devices are maintained within the table 400. Within this sequential order, if a device

mode has not been setup by the user (indicated by a “no” in the data field 440 for that device) this device mode will be skipped during the procedure.

More specifically, to initiate an “All On” procedure, for each device mode that has been setup, it is determined if a specific device supports explicit “On” and “Off” commands. This is determined by reference the command code library for the specified device using conventional look-up techniques. If the device supports these explicit commands, the remote control 10 merely transmits the explicit “On” command for that device to place the device in the “On” state and the procedure continues with the next device (if any).

10 If the device does not support explicit commands (i.e., it supports a power toggle command), the current status of the device is retrieved from the power status field 450 of the data table 400. If the status is indicated to be “Unknown” or “On,” no further processing for this device is performed and the procedure moves to the next device (if any). If, however, the status is indicated to be “Off” in the power status field 450, the power toggle command for that device is transmitted for the purpose of causing the device to enter the “On” state. In this manner, activation of the “All On” key avoids the inadvertent placing of a home appliance in an unwanted “Off” state.

In a similar fashion, activation of the “All Off” key avoids the inadvertent placing of a home appliance in an unwanted “On” state. In this regard, activation of the “All Off” key causes the transmission of an explicit “Off” command, the transmission of a power toggle command, or no action in accordance with the logic set forth above with respect to the “All On” procedure.

Still further, the table 400 can be updated and the data contained therein considered in the performance of the steps assigned to a programmed Macro key or in response to activation of the single unit power keys 360. Again, a transmission of a status enquiry message and the updating of the table 400 can be performed in response to  
5 activation of these keys. The processing in response to activation of these keys would be performed in the same manner described above with respect to the “All On”/”All Off” procedures excepting that it would be performed on an individual device basis as illustrated in Fig. 8.

By way of specific example, assuming a Macro key was programmed to turn the  
10 VCR device on, turn the TV device on, and tune the TV device to channel 3, activation of the Macro key would result in the updating of the table 400 (in the manner described above) and the processing of the macro command steps as follows (assuming the table 400 indicates that the VCR and TV devices were setup and the addresses of their respective power monitor units were also setup):

15           It is determined if the VCR and TV device support explicit “On” and “Off” commands.

          If a device supports these explicit commands, the remote control 10 merely transmits the explicit “On” command for the VCR and/or TV and the macro continues to the next step.

20           If the VCR and/or TV does not support explicit commands (i.e., it supports a power toggle command), the current status of the VCR and/or TV is retrieved from the power status field 450 of the data table 400.

If the status is indicated to be “Unknown” or “On,” no further processing for the device is performed and the macro moves to the next step (if any).

If, however, the status is indicated to be “Off,” the power toggle command for the VCR and/or TV is transmitted for the purpose of causing the VCR and/or TV to enter the “On” state and the next step in the macro chain is executed (if any).

In this manner, the remote control 10 ensures that execution of a macro or the single power on key will not place an appliance in an undesired state.

The ability of a power monitor 14 to determine the operational state of an appliance, e.g., on or off, playing or not playing, etc., may also be utilized to effect automatic setup of the remote control 10. As illustrated in Fig. 15, setup of the remote control 10 to command an appliance may be initiated by the user indicating a desire to enter a remote control 10 setup mode. By way of example only, this desire may be indicated to the remote control 10 by the user actuating the setup key 310 and entering a unique setup code number, e.g. "991", to initiate the automatic setup process. Where multiple device mode keys 330 are available, this setup process may also include the user actuating one of the device mode keys 330 for the purpose of informing the remote control 10 which of the device modes is being assigned to the commands that are to be used to command the operation of the appliance.

Once a setup mode has been entered, the remote control 10 may then be caused to transmit one or more commands selected from command code sets within the library of command sets to the appliance that the remote control is to be setup to command the operation of for the purpose of causing that appliance to perform an action that will, in

turn, cause a change in state in the appliance that will be discernable by the power monitoring unit 14 that is associated with that appliance. By way of example, the transmitted commands may directly command the appliance to change power, e.g., a power on, power off, or power toggle command, or may indirectly cause the appliance to change power, e.g., a VCR play or audio receiver input selection command which also causes the appliance to turn on. While not required, it may be preferred to limit the commands transmitted to those that are appropriate for the type of device the remote control is being setup to operate. For example, if the user indicates that the device is a television, for example by actuating a “TV” device mode key 330 during the setup process, only those commands that have been designated as controlling televisions may be selected from the library of command sets. It will also be appreciated that selected commands may be transmitted automatically on a periodic basis or may require the user to manually step through the commands that are to be transmitted (for example by actuating the power button in response to which the remote control transmits a power command selected from one of the command sets, the next actuation then sending a power command from a next one of the command sets). It will be additionally appreciated that the order in which the commands are selected for transmission from the command sets may be predetermined, for example as a function of the installed base of consumer equipment appropriate to a particular geographic or demographic market, such that commands for commanding operations of more popular devices are transmitted first.

When the appliance responds to a command transmitted from the remote control 10, the power monitor 14 will sense the change in power state of the appliance. The sensed change in the power state of the appliance may then be reported to the remote

control 10 via transmission of data that functions to inform the remote control 10 that a change in power state was detected by the power monitor 14. For this purpose, the power monitor 14 may have been configured, for example in the manner discussed previously, to discern absolute changes in the power state of the appliance based on a threshold value  
5 or may be adapted to simply report relative changes in power draw as described earlier. In response to the receipt of this status data from the power monitor 14, the remote control 10 may then automatically set itself up to utilize the command set that included the transmitted command that caused the appliance to respond with the change in state that was discerned by the power monitor 14 as the command set for remotely controlling  
10 operations of that appliance.

It will be appreciated that in the event an ambiguity remains as to the specific appliance command set, for example if it is known that multiple command sets exist which share a common “power on” code, the remote control may optionally transmit additional command signals (e.g., “pla””) selected from the ambiguous subset of codes  
15 while continuing to monitor power status changes, in order to uniquely identify the appropriate command set for the appliance. Alternatively, in such cases the remote control may simply exit the setup mode as described above to allow the user to experiment with the first command set identified. Should the first command set be found inadequate, the remote control may for example be adapted to resume the search from the  
20 point where it previously left off, upon re-entry into the setup mode by the user. It will also be appreciated that in some instances it may be desirable for the power monitor 14 to associate with the status data reported an indication of the ID number of the power monitor unit, whereby this number may be used to further automatically setup the remote

control 10 to receive data from and/or communicate with the power monitor 14 for the purposes discussed previously. To this end, the power monitor ID number may be explicitly included as part of the status data transmitted or may be implied, for example based on the order in which power monitor responses are received as illustrated in Figure 5 12.

It will also be appreciated that the aforementioned method for setting up a remote control may be utilized to automatically setup the remote control across each device mode available to the remote control (e.g., TV, VCR, DVD, CD, etc.) or plural device modes designated by a user. In such a case, the remote control may step through each of 10 the available device modes and in each device mode would sequentially transmit commands from appropriate command code sets. If a status change report is received from a power monitor the remote control would utilize the command code set including the command that caused the response in the appliance as the command code set for controlling in appliance in that device mode. If no status change report is received from 15 any power monitor, after the remote control has attempted to transmit a command from all of the available command code sets for that device mode, the remote control may simply leave that device mode un-setup or set to a predefined default and then proceed to attempt to setup the next device mode, if any.

While specific embodiments of the present invention have been described in 20 detail, it will be appreciated by those skilled in the art that various modifications and alternatives to those details could be developed in light of the overall teachings of the disclosure. For example, it is contemplated that several current monitor modules 990 may be combined with a single microprocessor and RF transceiver 980 into a smart

power strip 900 for use in an entertainment center, as illustrated in Figs. 13 and 14. In this case, the method of operation and the processing logic is essentially the same as described previously excepting that, in this case, upon receipt of a power status query from the remote control 10 the microprocessor 66 will poll each power outlet and  
5 transmit a corresponding number of sequential status reply messages to the remote control 10. Each power outlet in the strip 900 can be assigned a unique address by the user or the user can set one number for the power strip which causes the outlets to be automatically assigned sequential addresses starting with the user set number. This approach allows power strips 900 and individual monitor modules 14 to be intermixed  
10 transparently to the remote control logic. Still further, it will be appreciated that a single power monitor module 990 could be switched between multiple power outlets using triacs or similar power switching apparatus under control of the microprocessor 66. Still further, the power strip may be adapted to modulate RF to IR to thereby receive RF signals and blast IR commands to appliances. Accordingly, it will be understood that the  
15 particular arrangements and procedures disclosed are meant to be illustrative only and not limiting as to the scope of the invention which is to be given the full breadth of the appended claims and any equivalents thereof.
